## Problem 1

0
(0)
-
$0 \rightarrow c$

The figure above represents the photons in a beam of light with some fixed wavelength and intensity. If size represents photon energy in the picture, which of the pictures below best representes a beam of light with half the wavelength but double the intensity?
half wavelength:
A) © © © © $\square$

D) $\bullet \bullet \bullet \bullet \bullet \bullet \bullet \rightarrow$

$$
\begin{aligned}
& \Rightarrow \text { double frequency } \quad\left(f=\frac{c}{\lambda}\right) \\
& \Rightarrow \text { double energy/photon } \quad(E=h f)
\end{aligned}
$$

since each photon has twice the
energy, need same $\# /$ second to get twice the intensity

## Problem 2

A physicist sets up a series of polarizers and finds that photons which are initially polarized in the vertical direction pass through all the polarizer with a net probability of exactly one quarter. If we send in a beam of vertically polarized light with an intensity $1600 \mathrm{~W} / \mathrm{m}^{2}$ through this series of polarizers, the intensity of the transmitted beam will be
A) $100 \mathrm{~W} / \mathrm{m}^{2}$
(B) $400 \mathrm{~W} / \mathrm{m}^{2}$
C) $800 \mathrm{~W} / \mathrm{m}^{2}$
D) $1600 \mathrm{~W} / \mathrm{m}^{2}$
E) $6400 \mathrm{~W} / \mathrm{m}^{2}$

$$
\begin{aligned}
& \text { Intensity reduction } \\
& =\text { probability that any single } \\
& \text { photon will go through. } \\
& \therefore I_{\text {tronsm }}=\frac{1}{4} I_{0}=400 \mathrm{~W} / \mathrm{m}^{2}
\end{aligned}
$$

## Problem 3

An unstable nucleus of mass M decays into another nucleus of mass m by emitting an $\alpha$ particle. The original mass M is BEFORE:
(A) Greater than $m+m_{\alpha}$
B) Less than $m+m_{\alpha}$
C) Equal to $m+m_{\alpha}$
D) Could be any of the above.

$$
\begin{aligned}
& \text { AFTER: } \\
& \text { energy conservation i } \\
& M c^{2}=m c^{2}+m_{\alpha} c^{2}+\text { kinetic energy } \\
& \therefore M>m+m_{\alpha}
\end{aligned}
$$

## Problem 4

Two protons (each with mass $938 \mathrm{GeV} / \mathrm{c}^{2}$.) traveling with equal speeds close to the speed of light in opposite directions collide to produce a new particle of mass M. Assuming that no other particles are produced in the collision, the mass M must be
A) less than $1876 \mathrm{GeV} / \mathrm{c}^{2}$.

BEFORE:
B) equal to $1876 \mathrm{GeV} / \mathrm{c}^{2}$.
C) greater than $1876 \mathrm{GeV} / \mathrm{c}^{2}$.
D) Any of the above are possible.

$$
\text { energy cons: } M=2 \gamma \underset{\uparrow_{\text {greater than } 2} m_{p}>1876 \mathrm{Gev} / \mathrm{c}^{2}}{ }
$$

BEFORE:

## Problem 5

A photon of wavelength $\lambda$ scatters off an electron that is initially stationary. After the collision, the photon's wavelength will be
A) equal to $\lambda$
B) greater than $\lambda$ AFTER
C) less than $\lambda$
D) any of the above are possible

$$
\begin{gathered}
\text { photon gives some of its energy } \\
\text { to electron } \therefore \lambda^{\prime}>\lambda
\end{gathered}
$$

Problem 6
Four photons are sent into a polarizer oriented at $90^{\circ}$ to the vertical. Their polarization states are

$$
\left|90^{\circ}\right\rangle, \quad \quad\left|0^{\circ}\right\rangle, \quad \quad\left|45^{\circ}\right\rangle, \quad \text { and } \quad \frac{1}{\sqrt{2}}\left|0^{\circ}\right\rangle-\frac{1}{\sqrt{2}}\left|90^{\circ}\right\rangle
$$

What are the possibilities for how many photons will pass through the polarizer?
$\left.190^{\circ}\right\rangle \rightarrow$ definitely through
A) exactly 1 photon will pass through
B) either 1 or 2 photons will pass through
C) either 1, 2, or 3 photons will pass through
D) either 2 or 3 photons will pass through
$\left|0^{\circ}\right\rangle \rightarrow$ definitely not
$\left.145^{\circ}\right\rangle \rightarrow$ maybe ( $50 \%$ prob)

$$
=\frac{1}{\sqrt{2}}\left|0^{\circ}\right\rangle+\frac{1}{\sqrt{2}}\left|20^{\circ}\right\rangle
$$ $=\frac{1}{\sqrt{2}}\left|0^{\circ}\right\rangle+\frac{1}{\sqrt{2}}\left|20^{\circ}\right\rangle$

E) any number ( $0,1,2,3$, or 4 ) might pass through $\frac{1}{\sqrt{2}}$ $\left|0^{\circ}\right\rangle-\frac{1}{\sqrt{2}}\left|90^{\circ}\right\rangle \rightarrow$ maybe ( $50 \%$ prob)

Problem 7

Suppose we build a sealed box which contains a battery connected to a heater which gradually heats the air inside the box. Assuming the box is completely isolated, and that the box neither absorbs nor emits any particles or radiation, what happens to the mass of the box (including its contents) as time passes?
A) The mass increases.

$$
\text { Mass }=\text { total energy of object }
$$ in its rest. frame

B) The mass decreases.
(C) The mass stays the same.
total energy of box must be conserved
$\therefore$ mass doesn't change with time

Problem 8

A beam of light with frequency $7.5 \times 10^{14} \mathrm{~s}^{-1}$ is incident on a metal, and photoelectrons are observed with maximum velocity $5 \times 10^{5} \mathrm{~m} / \mathrm{s}$. The same sample of metal is illuminated with a new light source, but this time electrons are observed with maximum velocity $10^{6} \mathrm{~m} / \mathrm{s}$. What is the frequency of the new light source? (3 points)

Have: $E_{k}^{\max }=h f-W$

$$
\begin{array}{rlrl}
\therefore \frac{1}{2} m v_{1}^{2} & =h f_{1}-W \quad v_{1}=5 \times 10^{5} \mathrm{~m} / \mathrm{s} \\
\Rightarrow w & =h f_{1}-\frac{1}{2} m v_{1}^{2} & f_{1}=7.5 \times 10^{14} \mathrm{~s}^{-1} \\
\frac{1}{2} m v_{2}^{2} & =h f_{2}-w \quad v_{2}=10^{6} \mathrm{~m} / \mathrm{s} \\
\Rightarrow f_{2} & =\frac{1}{h}\left(\frac{1}{2} m v_{2}^{2}+W\right) \\
& =\frac{1}{h}\left(\frac{1}{2} m v_{2}^{2}+h f_{1}-\frac{1}{2} m v_{1}^{2}\right) \\
& =f_{1}+\frac{m}{2 h}\left(v_{2}^{2}-v_{1}^{2}\right) \\
& =7.5 \times 10^{14} \mathrm{~s}^{-1}+\frac{9.1 \times 10^{-31} \mathrm{~kg}}{2 \times 6.6 \times 10^{-34} \mathrm{~J} \cdot \mathrm{~s}}\left(\left(10^{6} \mathrm{~m} / \mathrm{s}\right)^{2}-\left(5.1 \mathrm{~m}^{2} \mathrm{~s} / \mathrm{s}^{2}\right)\right. \\
\Rightarrow f_{2} & \approx 1.3 \times 10^{15} \mathrm{~s}^{-1}
\end{array}
$$

Problem 9
A photon with energy 100 MeV is incident on a stationary particle of mass $200 \mathrm{MeV} / \mathrm{c}^{2}$. If the photon is completely absorbed to form a new particle, what is the speed of this new particle (relative to the speed of light)?

BEFORE:

$$
\begin{aligned}
& E=100 \mathrm{MeV} \\
& \text { (M) }=200 \mathrm{MeV} / \mathrm{c}^{2}
\end{aligned}
$$

AFTER:
let $\tilde{M}=$ mass of final particle.

Momentum conservation $\Rightarrow P_{i}=P_{f}$

$$
\begin{align*}
& \frac{E}{c}=\gamma \widetilde{M} V \\
\Rightarrow & \frac{100 M \mathrm{VV}}{c}=\gamma \widetilde{M} V \tag{+}
\end{align*}
$$

Divide (+) by (*):

$$
\begin{aligned}
& \frac{V}{c^{2}}=\frac{100 \mathrm{MeV} / \mathrm{c}}{300 \mathrm{MeV}} \\
& \Rightarrow V=\frac{1}{3} \mathrm{c}
\end{aligned}
$$

$$
\begin{aligned}
\text { OR: } & E_{f}=E_{i}=300 \mathrm{MeV} \\
P_{f}=P_{i} & =\frac{100 \mathrm{MeV}}{c} \\
V_{f}= & \frac{P_{f}}{E_{f}} \cdot c^{2}=\frac{1}{3} c
\end{aligned}
$$

original frame:S

Problem 10

velocity of $S^{\prime}$ in $S$

$$
v=0.8 c \quad \gamma=\frac{5}{3}
$$

In some frame of reference, a photon with energy 10 eV is traveling in the negative x direction. According to an observer traveling at speed 0.8 c in the positive x direction relative to the original frame, what is the energy of the photon?
(2 points)

Use Lorentz Transform. for energy:

$$
\begin{array}{rlrl}
E^{\prime} & =\gamma\left(E-V p_{x}\right) & E=10 \mathrm{eV} \\
& =\frac{5}{3}\left(10 \mathrm{eV}-(0.8 \mathrm{c})\left(-\frac{10 \mathrm{eV}}{c}\right)\right) \\
& =\frac{5}{3}(10 \mathrm{eV}+8 \mathrm{eV}) \\
\Rightarrow E_{x}^{\prime} & =30 \mathrm{eV}
\end{array}
$$
